Validating data

Ivan is a data analyst working on an annual sales report for a popular ice cream chain. Answer the questions Ivan faces as he validates data for his report.

Data problem

Ice cream club members get free ice cream for their birthday. After running a query to see how many members got their free ice cream last year, Ivan noticed some null values.

The head of marketing explained to Ivan that members can visit as many locations as they want on their birthday. Ivan realized this meant the field should not be defined as a yes/no binary. Instead, it is better represented as a numeric value, up to the actual number of locations visited.

Data problem

To track all sales, Ivan assigned a primary key to every item on the menu from 1 to 60. After running a query to find the most popular menu items, he wondered why he couldn't find any beverage sales.

After reviewing the table, he realized he forgot to assign values to the five beverages on the menu, so he added those to the menu table, bringing the range to 1 to 65.

Data problem

Ivan ran a query to discover the top neighborhoods where ice cream club members live.

After running the query, he noticed that several zip code results contained letters—but in his country, zip codes can only contain numeric values.

Data problem

Ivan wanted to measure how long ice cream pint inventory sits in company freezers. He ran a query to pull pint production dates and shipping dates. Next, he noticed that some production dates came after their shipping date. This told Ivan there must be an error in the data.

Data problem

After working with an advertising agency, the ice cream shop received five different jingle options to use in their new commercial. Ivan stored these files in his database as MP3 files.

When he ran a query for the jingles, he got null values. He went back into the database to see why the MP3 files wouldn't show up.

Data problem	Type of data validation
After clearly defining that zip code values must have only numeric values, Ivan ran his query again to find out where club members live. But he noticed some results had six or more values. Zip codes in his country should only have five numeric digits. So he went back to verify that the endings of strings are better defined within the table. You're done!

Data validation is all about ensuring data integrity. Your goal during this process should be to make sure data is complete, accurate, secure, and consistent.
