

Hamza: How Python helped my data science career

My name is Hamza and I'm an applied machine learning engineer. I love building models, I love building large-scale systems and that is exactly what I do at work. It's a form of art for me, that you get to create something from scratch that does not exist and you put it into production and it is used by about a hundred million users. The scope of my work is to build, maintain, and production allies large-scale models. So, Python is pretty much the central theme of my job. Python is a programming language which helps you manipulate data, which helps you build models and you can use it to create production level models and softwares. There are a lot of other programming languages which will do the same things that you're looking for.

For me personally, I use Python because there's a lot of documentation, there's a lot of help. And there is a lot of learning from past failures from different programming languages which has been incorporated to help Python be user-friendly and be used by everyone around and easy to adapt. You never get hired as a good chef because you have good knives, you get hired as a good chef because you have good cooking skills. This is the same thing. Python has helped me become a better data scientist, better machine learning engineer. And it has helped me understand diverse set of

mathematical applications in machine learning which previously I was not aware of. I

think the unique strength about Python is that it's just some multifaceted tool.

It's not just one thing, it's not for just for data manipulation or data cleaning, you can do transformations, data cleaning, you can build models, you can put them into production, you can make an API out of it, you can build monitoring systems on top of that. Those are the strengths of Python, that makes you sort of master of all in when it comes to data science. The one most important thing that when you do an online course you're studying anything is that learning is not linear, there's a very steep curve, and then eventually you just get to the, aha, moment. The thing is that in the first two weeks when you're doing a certain course, you might be, okay, this is not making sense and it's not working for me and it's not doing what I'm looking for, so just stick to it and be consistent. The learning curve is always deep in these things but then you eventually get to a point where you say, I know all of these things and I can put all the knowledge that I have together to build something great.

"It's a form of art for me, that you get to create something from scratch that does not exist and you put it into production and it is used by about a hundred million users."

"Python has helped me become a better data scientist, a better machine learning engineer."
