

Test your knowledge: Lists and tuples

1. Lists and their contents are immutable, so their elements cannot be modified, added, or removed.

1 / 1 point

- ☐ True
- ☒ False

✓ Nice work

Lists and their contents are mutable, so their elements can be modified, added, or removed. A list is a data structure that helps store and manipulate an ordered collection of items.

2. What Python method adds an element to the end of a list?

1 / 1 point

- ☐ `type()`
- ☐ `remove()`
- ☒ `append()`
- ☐ `pop()`

✓ Nice work

Python's `append()` method adds an element to the end of a list.

3. A data professional wants to instantiate a tuple. What Python elements can they use to do so? Select all that apply.

1 / 1 point

- ☐ Square brackets
- ☒ The `tuple()` function

✔ Nice work

A data professional can use parentheses or the `tuple()` function to instantiate a tuple. A tuple is an immutable sequence that can contain elements of any data type.

- ☐ The `insert()` function
- ☒ Parentheses

✔ Nice work

A data professional can use parentheses or the `tuple()` function to instantiate a tuple. A tuple is an immutable sequence that can contain elements of any data type.

4. What Python technique formulaically creates a new list based on the values in an existing list?

1 / 1 point

- ☐ List conversion
- ☐ List nesting
- ☒ List comprehension
- ☐ List sequencing

✔ Nice work

A list comprehension formulaically creates a new list based on the values in an existing list. A list comprehension functions like a `for` loop, but is a more efficient and elegant way to create a new list from an existing list.
