

Create engaging data visualizations with AI

It happens sometimes in data analysis. You end up with fantastic findings, but can't really convey them in an attention-grabbing way. That's why data visualization matters. To share what we learn, we need to create compelling, informative, impactful charts and graphs that highlight key insights. Data visualization is an area where gen AI can really help save you a lot of time. Imagine you need to present sales data trends over the past year. A gen AI tool can tell you which charts and graphs to create and how to do it. And with more advanced AI tools like Gemini and Google Sheets, AI can create those visualizations for you and make sure they're accurate and consistent. So let me share an example. Suppose it's my job to visualize the marketing sales performance of my organization. This is a complex task. In between the cleaning, analysis prep, and everything else that comes with it, it's probably going to take a lot of time. I'm going to use a gen AI tool to get some help here. First, I set the context or give a small summary of my data.

For example, I could begin my prompt with something like, I have a data set that tracks the performance of marketing campaign sales over the last year, including metrics such as click-through rates, conversion rates, and ROI. Next, I'll get into my task, and add something like, identify potential visualizations that will effectively communicate the performance trends and insights from these campaigns. And just like that, we have a list of several possible visualizations that would effectively communicate the performance trends and insights from the marketing campaign dataset. Now, let's say you wanna learn more about the types of charts that were suggested in the output. One way you can iterate on your prompt is to ask the gen AI tool to show you YouTube videos or links from Google search about the types of charts it's suggested. Keep in mind that in this

example, we're using Gemini to generate the steps for creating these visualizations, as we aren't uploading any actual data. However, if you're working with an enterprise level AI tool, you can upload data directly, so that the tool can generate visualizations for you, streamlining the process significantly.

One of the things I like most about using gen AI to come up with these ideas for data visualizations is that it lets me focus more on interpreting the data and sharing my insights, and less on the technical aspects of creating visuals. And that's a much more productive use of my time. Before we wrap up this example, I wanna leave you with a pro tip. Up until now, I've been typing prompts in the Gemini. If you don't want to type, you can also activate the microphone feature. This lets you quickly add more information, start a new prompt, or iterate on an existing prompt, all using your voice.
