

Cloud computing service model

[00:00](#) Here, at Google, we have many data centers.

[00:03](#) A data center is a physical building that contains servers, computer systems, and associated components.

[00:10](#) These facilities provide a centralized location for vast amounts of data.

[00:14](#) And skilled cloud analysts access this valuable information right through the cloud!

[00:20](#) For all sorts of business tasks and projects, cloud analysts select and extract relevant data, then prepare it for processing and examination.

[00:29](#) They know how to expertly analyze, visualize, and share data discoveries to uncover valuable insights and make smart business decisions.

[00:38](#) So it's really important to know that there are three primary models to choose from.

[00:43](#) Each offers a different level of flexibility and control.

[00:48](#) These models are **infrastructure as a service, or IaaS**; **platform as a service, PaaS**; and **software as a service, SaaS**.

[00:58](#) First, **IaaS is a cloud computing module that offers on-demand access to Information Technology, or IT infrastructure services, including hardware, storage, network, and virtualization tools**.

[01:16](#) With IaaS, **a service provider hosts, maintains, and updates the infrastructure**.

[01:23](#) Your organization would manage everything else: your operating system, your data, and your applications.

[01:29](#) An **IaaS model provides the highest level of control over your IT resources and works a lot like traditional on-premises IT**.

[01:39](#) An example of **an IaaS model is cloud storage, like emails you've sorted into an online folder**.

[01:46](#) Here's another example.

[01:48](#) When someone leases a car, it's like they're borrowing it for a while, having fun

[01:51](#) driving it around, but they have to give it back when the lease agreement is up.

[01:56](#) Well, IaaS is kind of like that.

[01:58](#) A user picks the infrastructure they want, uses it for the contracted period, but they do not own it.

[02:05](#) Next, PaaS provides hardware and software tools to create an environment for the development of cloud applications, simplifying the application-development process.

[02:18](#) PaaS is all about helping users build apps.

[02:21](#) So, your organization would enjoy being able to fully focus on app development without the burden of managing and maintaining the underlying infrastructure.

[02:30](#) Your developers would create, test, troubleshoot, launch, host, and maintain your app all on the platform.

[02:40](#) PaaS is like hopping into a taxi and telling the driver where to take you.

[02:44](#) You're not behind the wheel, but you trust the driver to get you to where you need to be.

[02:49](#) Lastly, SaaS provides users with a licensed subscription to a complete software package.

[02:56](#) This includes the infrastructure, maintenance and updates, and the application itself.

[03:01](#) Other users also have access to use the same services.

[03:05](#) Using SaaS, you'd just connect to the app through the internet.

[03:09](#) Think of SaaS like riding the bus —you pick your stop from routes that are set already and you share the bus ride with other people.

[03:17](#) Remember that these examples are meant to demonstrate the level of individual customization in IaaS, PaaS, and SaaS.

[03:28](#) They do not refer to any actual hardware or software details.

[03:33](#) Whew!

[03:34](#) We've covered a lot about cloud computing, infrastructure, and service models.

[03:38](#) I think we've earned ourselves a study snack.

[03:41](#) I'm gonna go cook something up in my cloud kitchen.

[03:44](#) Catch ya later!
